**A Method of Cleaning by Removing Particles from Surfaces, a Cleaning Apparatus  
and a Lithographic Projection Apparatus**

The present invention relates to a method of cleaning by removing particles from sensitive surfaces. It is used particularly in conjunction with a lithographic projection apparatus comprising:

- a radiation system for supplying a projection beam of radiation;
- 5 - a support structure for supporting patterning means, the patterning means serving to pattern the projection beam according to a desired pattern;
- a substrate table for holding a substrate; and
- a projection system for projecting the patterned beam onto a target portion of the substrate.

10

The term "patterning means" as here employed should be broadly interpreted as referring to means that can be used to endow an incoming radiation beam with a patterned cross-section, corresponding to a pattern that is to be created in a target  
15 portion of the substrate; the term "light valve" can also be used in this context. Generally, the said pattern will correspond to a particular functional layer in a device being created in the target portion, such as an integrated circuit or other device (see below). Examples of such patterning means include:

- A mask. The concept of a mask is well known in lithography, and it includes mask  
20 types such as binary, alternating phase-shift, and attenuated phase-shift, as well as various hybrid mask types. Placement of such a mask in the radiation beam causes selective transmission (in the case of a transmissive mask) or reflection (in the case of a reflective mask) of the radiation impinging on the mask, according to the pattern on the mask. In the case of a mask, the support structure will generally be a  
25 mask table, which ensures that the mask can be held at a desired position in the incoming radiation beam, and that it can be moved relative to the beam if so desired.
- A programmable mirror array. One example of such a device is a matrix-

addressable surface having a viscoelastic control layer and a reflective surface. The basic principle behind such an apparatus is that (for example) addressed areas of the reflective surface reflect incident light as diffracted light, whereas unaddressed areas reflect incident light as undiffracted light. Using an appropriate filter, the said undiffracted light can be filtered out of the reflected beam, leaving only the diffracted light behind; in this manner, the beam becomes patterned according to the addressing pattern of the matrix-addressable surface. An alternative embodiment of a programmable mirror array employs a matrix arrangement of tiny mirrors, each of which can be individually tilted about an axis by applying a suitable localized electric field, or by employing piezoelectric actuation means. Once again, the mirrors are matrix-addressable, such that addressed mirrors will reflect an incoming radiation beam in a different direction to unaddressed mirrors; in this manner, the reflected beam is patterned according to the addressing pattern of the matrix-addressable mirrors. The required matrix addressing can be performed using suitable electronic means. In both of the situations described hereabove, the patterning means can comprise one or more programmable mirror arrays. More information on mirror arrays as here referred to can be gleaned, for example, from United States Patents US 5,296,891 and US 5,523,193, and PCT patent applications WO 98/38597 and WO 98/33096, which are incorporated herein by reference. In the case of a programmable mirror array, the said support structure may be embodied as a frame or table, for example, which may be fixed or movable as required.

- A programmable LCD array. An example of such a construction is given in United States Patent US 5,229,872, which is incorporated herein by reference. As above, the support structure in this case may be embodied as a frame or table, for example, which may be fixed or movable as required.

For purposes of simplicity, the rest of this text may, at certain locations, specifically direct itself to examples involving a mask and mask table; however, the general principles discussed in such instances should be seen in the broader context of the patterning means as hereabove set forth.

Lithographic projection apparatus can be used, for example, in the manufacture of integrated circuits (ICs). In such a case, the patterning means may generate

a circuit pattern corresponding to an individual layer of the IC, and this pattern can be imaged onto a target portion (*e.g.* comprising one or more dies) on a substrate (silicon wafer) that has been coated with a layer of radiation-sensitive material (resist). In general, a single wafer will contain a whole network of adjacent target portions that are successively irradiated via the projection system, one at a time. In current apparatus, employing patterning by a mask on a mask table, a distinction can be made between two different types of machine. In one type of lithographic projection apparatus, each target portion is irradiated by exposing the entire mask pattern onto the target portion in one go; such an apparatus is commonly referred to as a wafer stepper. In an alternative apparatus — commonly referred to as a step-and-scan apparatus — each target portion is irradiated by progressively scanning the mask pattern under the projection beam in a given reference direction (the "scanning" direction) while synchronously scanning the substrate table parallel or anti-parallel to this direction; since, in general, the projection system will have a magnification factor  $M$  (generally  $< 1$ ), the speed  $V$  at which the substrate table is scanned will be a factor  $M$  times that at which the mask table is scanned. More information with regard to lithographic devices as here described can be gleaned, for example, from US 6,046,792, incorporated herein by reference.

In a manufacturing process using a lithographic projection apparatus, a pattern (*e.g.* in a mask) is imaged onto a substrate that is at least partially covered by a layer of radiation-sensitive material (resist). Prior to this imaging step, the substrate may undergo various procedures, such as priming, resist coating and a soft bake. After exposure, the substrate may be subjected to other procedures, such as a post-exposure bake (PEB), development, a hard bake and measurement/inspection of the imaged features. This array of procedures is used as a basis to pattern an individual layer of a device, *e.g.* an IC. Such a patterned layer may then undergo various processes such as etching, ion-implantation (doping), metallization, oxidation, chemo-mechanical polishing, etc., all intended to finish off an individual layer. If several layers are required, then the whole procedure, or a variant thereof, will have to be repeated for each new layer. Eventually, an array of devices will be present on the substrate (wafer). These devices are then separated from one another by a technique such as dicing or sawing, whence the individual devices can be mounted on a carrier, connected to pins, etc. Further information regarding such processes can be obtained, for example, from the book "Microchip Fabrication: A Practical

Guide to Semiconductor Processing", Third Edition, by Peter van Zant, McGraw Hill Publishing Co., 1997, ISBN 0-07-067250-4, incorporated herein by reference.

For the sake of simplicity, the projection system may hereinafter be referred to as the "lens"; however, this term should be broadly interpreted as encompassing various types of projection system, including refractive optics, reflective optics, and catadioptric systems, for example. The radiation system may also include components operating according to any of these design types for directing, shaping or controlling the projection beam of radiation, and such components may also be referred to below, collectively or singularly, as a "lens". Further, the lithographic apparatus may be of a type having two or more substrate tables (and/or two or more mask tables). In such "multiple stage" devices the additional tables may be used in parallel, or preparatory steps may be carried out on one or more tables while one or more other tables are being used for exposures. Dual stage lithographic apparatus are described, for example, in US 5,969,441 and WO 98/40791, incorporated herein by reference.

To ensure a sharp and clean image is imaged onto the substrate the mask is thoroughly cleaned before use. Any particles remaining on the surface of the mask could ruin the image and scratch the mask. As the critical dimensions of integrated circuits decrease, the scope for imaging error increases, and so the importance of eliminating stray particles is ever increasing. To avoid scratching particularly delicate masks, a non-contact method of cleaning is desirable. Present methods of non-contact cleaning include laser cleaning, burst cleaning or wet ultra-sound cleaning. However, with these methods there is a risk of damage to the mask due to the nature of vibrations induced in the particles.

It is an object of the present invention to provide a new and improved method of cleaning a mask or other object by removing particles from the surface of the mask or other object.

This and other objects are achieved according to the invention in a method of cleaning a surface of an object by removing particles from the surface of the object comprising the steps of:

- providing a chamber which can be sealed in an air tight manner;
- placing the object in said chamber with surface to be cleaned exposed;

- sealing said chamber; and
- reducing the gas pressure in said chamber to a low pressure, characterized in that the gas pressure is reduced quickly.

The inventors have found that reducing the gas pressure from atmospheric  
5 pressure to  $10^{-2}$  mbar achieves beneficial results. Further, the gas pressure drop should preferably take place over less than 5 seconds. To create a greater gas pressure differential the gas pressure can be increase prior to the quick pressure drop.

After quickly reducing the gas pressure, it can then be quickly increased,  
preferably to the original gas pressure before the gas pressure was reduced. For  
10 particularly thorough cleaning the gas pressure is repeatedly cycled between a low pressure and a higher pressure.

This cleaning method can be used in conjunction with other methods of removing particles. For example, an electric field can be used to attract and remove particles away from the surface. This would provide an additional force removing the  
15 particles. To increase this force further the surface of the object to be cleaned is charged. Alternatively, or additionally, the object vibrates, which helps to loosen any particles that may be caught on the surface of the object by static friction. Similarly, bombarding the surface of the object to be cleaned with particles helps remove immobile contaminant particles caught by static friction. Due to its inert nature and low price condensed  $\text{CO}_2$  has  
20 been found to be ideal for this purpose. Changing the temperature of the object can also help dislodge a particle, due to the consequential expansion or contraction of the material. These additional methods of removing particles can either take place during or prior to the chamber depressurization.

To decrease adhesion forces between the particle and the surface of the  
25 object to be cleaned a layer of liquid, preferably a solvent can be applied to the surface of the object to be cleaned.

This invention has been developed particularly for the cleaning of lithographic masks, although it is applicable to all other sensitive surfaces.

According to a further aspect of the invention there is provided an apparatus for  
30 removing particles from surfaces of objects comprising:

- a chamber with a door capable of being sealed in an air tight manner;
- means for reducing the gas pressure of the sealed chamber; and

at least one of the following:

means for providing an electric field to attract and remove the particles from the surface;

means for vibrating the object to be cleaned;

5 means for bombarding the surface of the object to be cleaned with particles; and

means for applying a layer of liquid of the surface of the object to be cleaned.

According to a further aspect of the invention there is provided a lithographic apparatus as specified in the opening paragraph, characterized in that it further comprises a  
10 device for removing particles from surfaces of objects comprising:

a chamber with a door capable of being sealed in an air tight manner;

means for reducing the gas pressure of the sealed chamber from atmospheric pressure to  $10^{-2}$  mbar in less than 5 seconds.

The present invention is therefore particularly applicable to lithography  
15 involving EUV radiation as this is an area of lithography which is particularly sensitive to errors.

Although specific reference may be made in this text to the use of the apparatus according to the invention in the manufacture of ICs, it should be explicitly understood that such an apparatus has many other possible applications. For example, it  
20 may be employed in the manufacture of integrated optical systems, guidance and detection patterns for magnetic domain memories, liquid-crystal display panels, thin-film magnetic heads, etc. The skilled artisan will appreciate that, in the context of such alternative applications, any use of the terms "reticle", "wafer" or "die" in this text should be considered as being replaced by the more general terms "mask", "substrate" and "target  
25 portion", respectively.

In the present document, the terms "radiation" and "beam" are used to encompass all types of electromagnetic radiation, including ultraviolet radiation (e.g. with a wavelength of 365, 248, 193, 157 or 126 nm) and EUV (extreme ultra-violet radiation, e.g. having a wavelength in the range 5-20 nm), as well as particle beams, such as ion  
30 beams or electron beams.

Embodiments of the invention will now be described, by way of example only, with reference to the accompanying schematic drawings in which:

Figure 1 depicts a cleaning apparatus according to a first embodiment of the  
5 invention;

Figure 2 shows the method of dislodging a particle;

Figure 3 depicts a cleaning apparatus with electrostatic attracting means according to a second embodiment of the invention;

Figure 4 depicts a cleaning apparatus with a vibrating object table according  
10 to a third embodiment of the invention;

Figure 5 depicts a cleaning apparatus in which the mask is bombarded by condensed CO<sub>2</sub> according to a fourth embodiment of the invention;

Figure 6 shows a cross-section of a mask with a layer of solvent; and

Figure 7 depicts a lithographic projection apparatus according to an  
15 embodiment of the invention.

In the Figures, corresponding reference symbols indicate corresponding parts.

20

#### Embodiment 1

Figure 1 shows an apparatus according to the invention with a chamber 10 having a door 11 which can be sealed in an air tight fashion, such that there can be a large pressure differential between inside and outside the chamber 10. A pipe 13 leads from the  
25 inside of the chamber 10 to pumping means 15 and inside the chamber there is an object table 14. A mask MA to be cleaned is fixed on the object table 14 with the surface to be cleaned 25 exposed. The mask MA should be firmly fixed to the object table 14 by, for example vacuum suction means. Once the door 11 has been sealed the pumping means reduce the gas pressure inside the chamber 10 from atmospheric pressure to 10<sup>-2</sup>mbar in  
30 about 1 second. The time to reduce the gas pressure can vary, but should not be more than 5 seconds. The inventors have conducted experiments to show that this rapid depressurization can successfully dislodge particles. It is not known exactly how the

depressurization dislodges the particles but a probable method is that as the gas is extracted from the chamber 10 very quickly, pockets of gas 27 caught behind the particles 26 dislodge the particles as shown in Figure 2. Another possible force dislodging the particles 26 is the turbulent flow of the gas which can knock the particles 26, therefore dislodging them. Once the particles 26 have been dislodged they are extracted from the chamber 10 with the air and then removed from the air stream. After decreasing the gas pressure the gas pressure is then increased back up to atmospheric pressure in 1 second. Rapidly increasing the gas pressure inside the chamber also generates turbulence and can pockets of air can similarly dislodge the particles. The cycle of decreasing the pressure from atmospheric pressure to a lower pressure and back up to atmospheric pressure can be repeated as many times as necessary.

The pressure does not have to be decreased to  $10^{-2}$  mbar, but the greater and faster the pressure drop the more effective the cleaning method. Thus, decreasing the pressure to  $10^{-7}$  mbar would be more advantageous still. Similarly, the gas pressure does not have to be rapidly decreased from 1 atmosphere. For example the gas pressure in the chamber could be increased to 10, or even 100 atmospheres to generate a greater rapid pressure drop to  $10^{-2}$  or  $10^{-7}$  mbar.

To reduce the adhesive forces between the particles 26 and the surface of the mask 25 to be cleaned the components of gas in the chamber 10 can be varied. Optimizing the gas mixture can also be used to improve, and increase the chances of, particle removal due to e.g. different viscosities.

## Embodiment 2

The second embodiment is the same as the first embodiment except for the features described in the following description.

As shown in Figure 3, there is a chargeable plate 32 in the chamber opposite the surface of the mask to be cleaned 25. In this embodiment the object table 14 is made of metal and can also be charged. At the same time as the rapid decrease in pressure of the chamber 10 a voltage source V charges the charged plate 32 and the object table 14 to between 10 and 2000 V. The mask MA on the object table 14 will therefore also become charged. As the mask MA is charged, the particles on it will be attracted towards the charged plate 32. There is therefore another force for dislodging the particles 26.

### Embodiment 3

The third embodiment is the same as the first embodiment except for the features described in the following description. In this embodiment the object table 14 vibrates during depressurization of the chamber 10, as shown in Figure 4. The vibrations shown in Figure 5 are linearly parallel to the plane of the mask MA and are of the order of 1mm. The frequency of vibration can be between 50 to 500Hz. One of the forces adhering the particles 26 to the mask MA is static friction. When the object table 14 (and also the mask MA since it is firmly fixed to the object table 14) changes direction during the vibration the inertia of the particles means that they continue to travel in the original direction while the mask MA changes direction beneath them. This overcomes the static friction and therefore dislodges the particles 26.

Instead of linear vibrations rotational vibrations parallel to the plane of the mask MA could also be used. These should be approximately 5° at a frequency of between 1 and 5000 Hz.

### Embodiment 4

The fourth embodiment is the same as the first embodiment except for the features described in the following description. In this embodiment, shown in Figure 5, condensed CO<sub>2</sub> is contained in a container 43 outside the chamber 10. The condensed CO<sub>2</sub> is projected through a one way valve 45 towards the mask MA at the same time as the chamber 10 is depressurized. When the particles of condensed CO<sub>2</sub> bombard the mask MA the force dislodges the particles 26 from the surface of the mask 25 to be cleaned. The condensed CO<sub>2</sub> evaporates and is extracted from the chamber 10 during the depressurization. This method is not restricted to the used of condensed CO<sub>2</sub>, and any inert liquid or solid in particle form could be used.

### Embodiment 5

The fifth embodiment is the same as the first embodiment except for the features described in the following description. A thin layer of solvent 52 is applied to the surface of the mask 25 to be cleaned prior to the depressurization of the chamber 10 as shown in Figure 6. The solvent reduces the adhesion forces between the particles 26 and the mask

MA, and dissolves the particles 26. The layer of solvent 52 should therefore be at least one layer molecular layer thick to ensure that the solvent is adjacent to all the particles 26 and preferably sufficiently thick to completely cover the particles 26 in order to dissolve or suspend the particles 26. As the gas pressure in the chamber is reduced and gas is  
5 extracted, the solvent, together with the dissolved or suspended particles will be extracted from the chamber 10. They can then be removed from the gas. The solvent can be varied to optimize the particles 26 solubility therein.

#### Embodiment 6

10 The apparatus described above can be used as an individual cleaning device, or it can be part of a larger lithographic apparatus. Figure 7 schematically depicts a lithographic projection apparatus in which a device described in any one of the previous embodiments could be incorporated. The apparatus comprises:

- a radiation system Ex, IL, for supplying a projection beam PB of radiation (*e.g.*  
15 EUV radiation), which in this particular case also comprises a radiation source LA;
- a first object table (mask table) MT provided with a mask holder for holding a mask MA (*e.g.* a reticle), and connected to first positioning means for accurately positioning the mask with respect to item PL;
- a second object table (substrate table) WT provided with a substrate holder for  
20 holding a substrate W (*e.g.* a resist-coated silicon wafer), and connected to second positioning means for accurately positioning the substrate with respect to item PL;
- a projection system ("lens") PL (*e.g.* a refractive) for imaging an irradiated portion of the mask MA onto a target portion C (*e.g.* comprising one or more dies) of the substrate W.

25 As here depicted, the apparatus is of a reflective type (*e.g.* has a reflective mask). However, in general, it may also be of a transmissive type, for example (*e.g.* with a transmissive mask). Alternatively, the apparatus may employ another kind of patterning means, such as a programmable mirror array of a type as referred to above.

The source LA (*e.g.* a laser-produced or discharge plasma source) produces a  
30 beam of radiation. This beam is fed into an illumination system (illuminator) IL, either directly or after having traversed conditioning means, such as a beam expander Ex, for example. The illuminator IL may comprise adjusting means AM for setting the outer

and/or inner radial extent (commonly referred to as  $\sigma$ -outer and  $\sigma$ -inner, respectively) of the intensity distribution in the beam. In addition, it will generally comprise various other components, such as an integrator IN and a condenser CO. In this way, the beam PB impinging on the mask MA has a desired uniformity and intensity distribution in its cross-section.

It should be noted with regard to Figure 1 that the source LA may be within the housing of the lithographic projection apparatus (as is often the case when the source LA is a mercury lamp, for example), but that it may also be remote from the lithographic projection apparatus, the radiation beam which it produces being led into the apparatus (e.g. with the aid of suitable directing mirrors); this latter scenario is often the case when the source LA is an excimer laser. The current invention and Claims encompass both of these scenarios.

The beam PB subsequently intercepts the mask MA, which is held on a mask table MT. Having been selectively reflected by the mask MA, the beam PB passes through the lens PL, which focuses the beam PB onto a target portion C of the substrate W. With the aid of the second positioning means (and interferometric measuring means IF), the substrate table WT can be moved accurately, e.g. so as to position different target portions C in the path of the beam PB. Similarly, the first positioning means can be used to accurately position the mask MA with respect to the path of the beam PB, e.g. after mechanical retrieval of the mask MA from a mask library, or during a scan. In general, movement of the object tables MT, WT will be realized with the aid of a long-stroke module (course positioning) and a short-stroke module (fine positioning), which are not explicitly depicted in Figure 1. However, in the case of a wafer stepper (as opposed to a step-and-scan apparatus) the mask table MT may just be connected to a short stroke actuator, or may be fixed.

The depicted apparatus can be used in two different modes:

1. In step mode, the mask table MT is kept essentially stationary, and an entire mask image is projected in one go (*i.e.* a single "flash") onto a target portion C. The substrate table WT is then shifted in the x and/or y directions so that a different target portion C can be irradiated by the beam PB;
2. In scan mode, essentially the same scenario applies, except that a given target portion C is not exposed in a single "flash". Instead, the mask table MT is movable in a

given direction (the so-called "scan direction", *e.g.* the *y* direction) with a speed  $v$ , so that the projection beam PB is caused to scan over a mask image; concurrently, the substrate table WT is simultaneously moved in the same or opposite direction at a speed  $V = Mv$ , in which  $M$  is the magnification of the lens PL (typically,  $M = 1/4$  or  $1/5$ ). In this manner, a  
5 relatively large target portion C can be exposed, without having to compromise on resolution.

Whilst specific embodiments of the invention have been described above, it will be appreciated that the invention may be practiced otherwise than as described. The description is not intended to limit the invention.

## CLAIMS:

1. A method of cleaning a surface of an object by removing particles from the  
5 surface of the object comprising the steps of:
  - providing a chamber which can be sealed in an air tight manner;
  - placing the object in said chamber with surface to be cleaned exposed;
  - sealing said chamber; and
  - reducing the gas pressure in said chamber to a low pressure,10 characterized in that the gas pressure is reduced quickly.
2. A method according to claim 1 wherein the gas pressure is reduced from atmospheric pressure to  $10^{-2}$  mbar.
- 15 3. A method according to either claim 1 or claim 2 wherein the gas pressure is reduced in less than 5 seconds.
4. A method according to any one of the preceding claims further comprising the subsequent step of quickly increasing the gas pressure.  
20
5. A method according to claim 4 wherein the gas pressure is quickly increased to the original gas pressure before the air pressure was reduced.
6. A method according to either claim 4 or claim 5 wherein the gas pressure is  
25 repeatedly cycled between a low pressure and a higher pressure.
7. A method according to any one of the preceding claims wherein the gas pressure is increased prior to reducing the gas pressure quickly.
- 30 8. A method according to any one of the preceding claims wherein the object is a lithographic mask.

9. A method according to any one of the preceding claims further comprising the step of providing an electric field to attract and remove the particles from said surface to be cleaned.

5 10. A method according to claim 9 wherein the surface of the object to be cleaned is charged to aid particle removal.

11. A method according to any one of the preceding claims wherein the object vibrates.

10 12. A method according to any one of the preceding claims wherein the temperature of the object changes.

13. A method according to any one of the preceding claims wherein particles  
15 bombard the surface of the object to be cleaned.

14. A method according to claim 13 wherein the bombarding particles are condensed CO<sub>2</sub>.

20 15. A method according to any one of the preceding claims further comprising the step of applying a layer of liquid to the surface of the object to be cleaned.

16. A method according to claim 15 wherein the layer of liquid is at least one molecular layer thick.

25 17. An apparatus for removing particles from surfaces of objects comprising:  
a chamber with a door capable of being sealed in an air tight manner;  
means for reducing the gas pressure of the sealed chamber; and  
at least one of the following:

30 means for providing an electric field to attract and remove the particles from the surface;  
means for vibrating the object to be cleaned;

means for bombarding the surface of the object to be cleaned with particles; and  
means for applying a layer of liquid of the surface of the object to be cleaned.

18. A lithographic projection apparatus comprising:

- 5 - a radiation system for providing a projection beam of radiation;
- a support structure for supporting patterning means, the patterning means serving to pattern the projection beam according to a desired pattern;
- a substrate table for holding a substrate;
- a projection system for projecting the patterned beam onto a target portion of the  
10 substrate,

characterized in that it further comprises a device for removing particles from surfaces of objects comprising:

a chamber with a door capable of being sealed in an air tight manner;

means for reducing the gas pressure of the sealed chamber from atmospheric

15 pressure to  $10^{-2}$  mbar in less than 5 seconds.

ABSTRACT

**A Method of Cleaning by Removing Particles from Surfaces, a Cleaning Apparatus  
5 and a Lithographic Projection Apparatus**

A lithographic mask is placed in a chamber which is then sealed in an air tight manner.  
The gas pressure in the chamber decreases rapidly from atmospheric pressure to  $10^{-2}$ mbar  
to dislodge contaminant particles on the mask surface.
